(57) **ABSTRACT**

A system includes a robotic arm on which at least one camera is attached. It further includes a memory and a controller communicatively coupled to the memory. The memory stores historical information associated with a dairy livestock. The historical information include a previously-determined location of a teat of the dairy livestock. The controller moves the camera on the robotic arm toward the previously-determined location of the teat. The camera generates an image of the teat of the dairy livestock from a position to which it is moved, and the controller determines a current location of the teat of the dairy livestock based at least in part on the image.

VISION SYSTEM FOR ROBOTIC ATTACHER**CROSS REFERENCE TO RELATED APPLICATIONS**

This application is a continuation of U.S. patent application Ser. No. 13/095,994, entitled "Vision System for Robotic Attacher," which was filed on Apr. 28, 2011, now U.S. Pat. No. 8,671,885, which is hereby incorporated by reference.

TECHNICAL FIELD

This invention relates generally to dairy farming and more particularly to a vision system for a robotic attacher.

BACKGROUND OF THE INVENTION

Over time, the size and complexity of dairy milking operations has increased. Accordingly, the need for efficient and scalable systems and methods that support dairy milking operations has also increased. Systems and methods supporting dairy milking operations, however, have proven inadequate in various respects.

SUMMARY OF THE INVENTION

According to embodiments of the present disclosure, disadvantages and problems associated with previous systems supporting dairy milking operations may be reduced or eliminated.

In certain embodiments, a system includes a controller operable to access a first image generated by a first camera. The controller determines a reference point from at least one main feature of a dairy livestock included in the first image. The controller is further operable to access a second image generated by the second camera. The second image includes at least a portion of an udder of the dairy livestock. The controller determines a location of a teat of the dairy livestock based on the second image.

Particular embodiments of the present disclosure may provide one or more technical advantages. For example, in some embodiments, the system of the present disclosure includes multiple cameras to facilitate locating the teats of a dairy livestock. Using multiple cameras may improve the visibility of the teats and may facilitate attaching milking equipment from a position to the rear of the cow, rather than to the side of the cow as in certain conventional systems. As another example, in some embodiments, the system of the present disclosure, in searching for the teats of a dairy livestock, may account for (1) a determined reference point relative to the dairy livestock, and/or (2) historical data describing a previous location of the teats relative to the reference point. Accounting for the determined reference point and/or the historical data in searching for the teats of a dairy livestock may allow for more accurate teat location, which may allow a robotic attacher to more efficiently attach milking equipment to the dairy livestock.

Certain embodiments of the present disclosure may include some, all, or none of the above advantages. One or more other technical advantages may be readily apparent to those skilled in the art from the figures, descriptions, and claims included herein.

BRIEF DESCRIPTION OF THE DRAWINGS

To provide a more complete understanding of the present invention and the features and advantages thereof, reference

2

is made to the following description taken in conjunction with the accompanying drawings, in which:

FIGS. 1A-1B illustrate example configurations of an enclosure **100** in which one or more milking boxes are installed, according to certain embodiments of the present disclosure;

FIG. 2 illustrates an example controller that may be used to control one or more components of the example milking box depicted in FIG. 1, according to certain embodiments of the present disclosure;

FIG. 3 illustrates a detailed perspective view of the example milking box depicted in FIG. 1, according to certain embodiments of the present disclosure;

FIG. 4 illustrates a detailed perspective view of the example robotic attacher depicted in FIG. 3, according to certain embodiments of the present disclosure;

FIG. 5 illustrates an example method for milking a dairy cow using the example milking box depicted in FIGS. 1-4, according to certain embodiments of the present disclosure; and

FIG. 6 illustrates an example method for installation of the example milking box depicted in FIGS. 1-4, according to certain embodiments of the present disclosure.

DETAILED DESCRIPTION OF THE DRAWINGS

FIGS. 1A-1B illustrate example configurations of an enclosure **100** in which one or more milking boxes **120** are installed, according to certain embodiments of the present disclosure. Enclosure **100** may be divided into a number of regions **110** (e.g., regions **110a** and **110b**), and each region **110** may include resting stalls, feeding troughs, walking paths, and/or other structure suitable for housing dairy livestock. Although the present disclosure contemplates enclosure **100** as housing any suitable dairy livestock (e.g., dairy cows, goats, sheep, water buffalo, etc.), the remainder of this description is detailed with respect to dairy cows.

Each milking box **120** may include a stall portion **122** configured to house a dairy cow being milked. The stall portion **122** of each milking box **120** may be defined by a number of walls **124**, each of which may each be constructed from any suitable materials arranged in any suitable configuration operable to maintain a dairy cow within stall portion **122** during milking. In certain embodiments, stall portion **122** of milking box **120** may include walls **124a**, **124b**, **124c**, and **124d**. For purposes of illustration, wall **124a** may be designated as the front of milking box **120** such that the head of a dairy cow being milked would be facing wall **124a**. Wall **124c** may be positioned opposite wall **124a** and may be designated as the rear of milking box **120**. Walls **124b** and **124d** may each form a side extending between the front and rear of milking box **120**. Walls **124a**, **124b**, **124c**, and **124d** may be spaced apart a suitable distance to ensure the comfort of the dairy cow within stall portion **122**.

Walls **124b** and/or **124d** may comprise one or more gates **126**. In certain embodiments, wall **124b** and/or wall **124d** may comprise an entry gate **126a** and an exit gate **126b**. A dairy cow may enter milking box **120** through an opened entry gate **126a** and exit milking box **120** through an opened exit gate **126b**. Closing gates **126** may maintain the dairy cow within milking box **120** during milking, while opening one or more gates **126** may allow the dairy cow to exit milking box **120**. In certain embodiments, gates **126** may each be coupled to a corresponding actuator such that the gates **126** may be automatically opened and/or closed. For example, the actuators corresponding to gates **126** may each

be configured to communicate (e.g., via wireless or wireline communication) with a controller 200, depicted in detail in FIG. 2.

Controller 200 may include one or more computer systems at one or more locations. Examples of computer systems may include a personal computer, workstation, network computer, kiosk, wireless data port, personal data assistant (PDA), one or more processors within these or other devices, or any other suitable device for receiving, processing, storing, and communicating data. In short, controller 200 may include any suitable combination of software, firmware, and hardware. Controller 200 may include any appropriate interface 210 for receiving inputs and providing outputs, logic 220, one or more processing modules 230, and memory module 240. Logic 220 includes any information, logic, applications, rules, and/or instructions stored and/or executed by controller 200. Processing modules 230 may each include one or more microprocessors, controllers, or any other suitable computing devices or resources and may work, either alone or with other components, to provide a portion or all of the functionality described herein. Controller 200 may additionally include (or be communicatively coupled to via wireless or wireline communication) one or more memory modules 240. Memory modules 240 may be non-transitory and may each include any memory or database module. Memory modules 240 may take the form of volatile or non-volatile memory, including, without limitation, magnetic media, optical media, random access memory (RAM), read-only memory (ROM), removable media, or any other suitable local or remote memory component.

Returning to FIG. 1, controller 200 may be operable to determine, using any appropriate logic in conjunction with signals received from other components of milking box 120 (e.g., presence sensor 132, gate sensors 134, and/or identification sensor 136, each of which is described with regard to FIG. 3, below), which gates 126 should be open and/or closed. Controller 200 may then communicate signals to the actuators coupled to the determined gates 126, the signals causing the gates 126 to open or close. The automated control of gates 126 using controller 200 is described in further with regard to FIG. 3, below.

Each milking box 120 may additionally include an equipment portion 128 located to the rear of stall portion 122 (i.e., adjacent to rear wall 124c of stall portion 122). Equipment portion 128 may comprise any structure suitable for housing and/or storing a robotic attacher (e.g., robotic attacher 150, described below with regard to FIG. 3), one or more preparation cups, teat cups, receiver jars, separation containers, and/or any other suitable milking equipment. Rear wall 124c (which may include a backplane 138, as described below with regard to FIG. 3) may separate stall portion 122 from equipment portion 128 such that equipment portion 128 is substantially inaccessible to a dairy cow located in stall portion 122. Accordingly a dairy cow located in stall portion 122 may be prevented from accidentally damaging the milking equipment by kicking, biting, trampling, or exposing the milking equipment to dirt, fluids, etc.

In certain embodiments, the equipment portion 128 being located to the rear of stall portion 122 may allow milking boxes 120 to be aligned in a single row such that walls 124b and 124d of each milking box 120 may comprise an entry gate 126a and an exit gate 126b (as illustrated in FIG. 1A). As a result, milking boxes 120 may be used to sort dairy cows into particular regions 110 by controlling the opening/closing of each gate 126 (e.g., in response to signals from a controller 200, as described above). For example, a dairy

cow needing a health check or medical attention may be sorted into an appropriate region 110 (e.g., a veterinary pen). As another example, a dairy cow determined to be finished milking for the year and needing to be dried off and bread may be sorted out of the milking heard. As yet another example, a dairy cow may be sorted into one of a number of regions 110 based on the stage of lactation of the dairy cow (as dairy cows in different stages may require different feeds).

In certain other embodiments, the equipment portion 128 being located to the rear of stall portion 122 may allow pairs of milking boxes 120 to be located side by side such that the milking boxes share a wall 124 (e.g., wall 124b may be shared between milking box 120c and milking box 120d, as depicted in FIG. 1B). As a result, a single robotic attacher (e.g., robotic attacher 150, described below with regard to FIG. 3) may be shared by the pair of milking boxes 120, which may reduce to cost of installing multiple milking boxes 120 in the enclosure 100.

FIG. 3 illustrates a detailed perspective view of an example milking box 120, according to certain embodiments of the present disclosure. As described above with regard to FIG. 1, milking box 120 may comprise a stall portion 122 (defined by walls 124 and gates 126) and equipment portion 128 located to the rear of stall portion 122. In certain embodiments, stall portion 122 of milking box 120 may include a feed bowl 130, a presence sensor 132, one or more gate sensors 134, and an identification sensor 136. Additionally, one or more of feed bowl 130, presence sensor 132, gate sensor(s) 134, and identification sensor 136 may be communicatively coupled to controller 200 (described above with regard to FIG. 2).

In certain embodiments, feed bowl 130 may dispense feed in order to attract a dairy cow so that the dairy cow will enter milking box 120 voluntarily. Accordingly, at least one of the entry gates 126a may remain open when there is no dairy cow present to allow a dairy cow to enter. Once the dairy cow has entered milking box 120, presence sensor 132 may detect the presence of the dairy cow. For example, presence sensor 132 may detect when the dairy cow has passed through the entrance gate 126a and/or when the dairy cow is generally centered in the stall portion 122. Upon detecting the presence of the dairy cow, presence sensor 132 may send a signal to controller 200. In response to the signal, controller 200 may cause one or more actuators to close gates 126. Gate sensor 134 may determine when gates 126 have closed. Gate sensor 134 may communicate a signal to controller 200 upon determining that gates 126 have closed. Controller 200 may initiate a milking procedure in response to the signal.

In certain embodiments, identification sensor 136 may determine the identity of the dairy cow. As an example, identification sensor 136 may comprise an antenna operable to read a radio frequency identification (RFID) from an ear tag, a collar, or other identifier associated with the dairy cow. Once the dairy cow has been identified, the identification sensor 136 may optionally be turned off to prevent wasting power and/or to minimize the dairy cow's exposure to radio waves.

Identification sensor 136 may communicate the identity of the dairy cow to controller 200 to facilitate retrieving information describing the dairy cow (e.g., from memory 240 or any other suitable location). Information describing the dairy cow may comprise historical data describing the particular dairy cow during a previous time period, such as a previous milking cycle. The previous milking cycle may refer to a milking cycle in which milking equipment was

5

manually attached (e.g., by a user) or a milking cycle in which milking equipment was automatically attached (e.g., by a robotic attacher **150**, described below). In certain embodiments, milking equipment may be attached manually the first time the dairy cow is milked in order to establish initial information describing the dairy cow, such as where the teats are located. The location of the dairy cow's teats may be described relative to a feature of the dairy cow, such as relative to the rear of the dairy cow, the hind legs, and/or a portion of the dairy cow's udder, such as a mid-line of the udder or relative to one or more of the other teats. A robotic attacher (e.g., robotic attacher **150**, described below) may use the information describing the location of the teats during subsequent milkings to facilitate automatically attaching the milking equipment.

Examples of historical data include measurements, statistics, health information, and any other information describing the dairy cow during a previous time period. Examples of measurements include the length of the dairy cow (e.g., from head to tail) and the location of the dairy cow's teats during a previous milking cycle. Examples of statistics may include statistics describing when the dairy cow was last milked, the amount of milk produced in previous milking cycles, and so on. Examples of health information may include a designation not to milk the dairy cow due to a health problem or a designation to sort the dairy cow into a veterinary pen. In certain embodiments, a user may set an indicator in the database to indicate that the dairy cow should be sorted into the veterinary pen because the dairy cow is due for a check-up or because the user noticed the dairy cow appears to be ill or injured.

Controller **200** may use the information retrieved according to the identity of the dairy cow to determine how the particular dairy cow should be handled. If the information indicates the dairy cow should not be milked, controller **200** may cause an actuator to open one or more of the exit gates **126b**. For example, if controller **200** determines that the dairy cow should be sorted into a particular region **110** of enclosure **100**, such as a veterinary pen, it may cause the exit gate **126b** that accesses the selected region **110** to open. Alternatively, controller **200** may cause multiple exit gates **126b** to open if the dairy cow is to be given the option of which region **110** to occupy upon exiting milking box **120**. In certain embodiments, a prod may be used to encourage the dairy cow to exit. Examples of prods include a noise, a mechanical device, or a mild electric shock.

Upon a determination that the dairy cow should be milked, controller **200** may continue the milking procedure. In certain embodiments, controller **200** may cause a dispenser to drop feed into feed bowl **130**. Additionally, controller **200** may cause feed bowl **130** to move toward the dairy cow in order to encourage the dairy cow to move to a pre-determined part of stall portion **122**. As an example, feed bowl **130** may be initially positioned in the front of stall portion **122** when the dairy cow enters. Feed bowl **130** may then move back toward the dairy cow to encourage the dairy cow to move to the rear of stall portion **122** (e.g., against backplane **138**, described below) in order to facilitate attaching the milking equipment to the dairy cow. To ensure feed bowl **130** does not crowd the dairy cow, the amount of movement of feed bowl **130** may be customized to the size of the dairy cow. For example, a user may determine an appropriate location for feed bowl **130** the first time the dairy cow enters milking box **120**. The location may be stored (e.g., in memory module **240** of controller **200**) such that it may be retrieved during subsequent milkings according to the identity of the dairy cow. Alternatively, the feed bowl

6

130 may be configured to continue moving toward the rear of the stall portion **122** until the dairy cow contacts backplane **138** (described below), which may indicate that the dairy cow is positioned in a location that is suitable for attaching the milking equipment.

In certain embodiments, rear wall **124c** of stall portion **122** includes a backplane **138**. Backplane **138** may comprise any suitable configuration of materials suitable for locating the rear of the dairy cow in order to facilitate the efficient attachment of the milking equipment. In certain embodiments, the dairy cow may be backed toward backplane **138** by moving feed bowl **130** as described above. In certain other embodiments, backplane **138** may be moved forward toward the dairy cow. In certain other embodiments, a combination of backing the dairy cow toward backplane **138** and moving backplane **138** forward toward the dairy cow may be used. It may be determined that the rear of the dairy cow has been located when a portion of backplane **138**, such as a pipe or bracket, touches the rear of the dairy cow at any suitable location, such as approximately mid-flank (i.e., between the udder and the tail). Backplane **138** may additionally include a manure gutter for directing manure toward a side of stall portion **122** (e.g., away from the dairy cow's udder and the milking equipment).

In certain embodiments, stall portion **122** may additionally include a waste grate **140** for disposing of waste. Waste grate **140** may have a rough surface to discourage the dairy cow from standing on it. In addition, waste grate **140** may be dimensioned such that when the dairy cow's hind legs are positioned on opposite sides of waste grate **140**, the hind legs are separated to facilitate attachment of the milking equipment to the dairy cow's teats.

In certain embodiments, equipment portion **128** of milking box **120** may include a robotic attacher **150**, one or more preparation cups **166**, teat cups **168**, pumps **170**, receiver jars **172**, milk separation containers **174**, and/or any other suitable milking equipment. In certain embodiments, robotic attacher **150** may be suspended into equipment portion **128** from a rail **160**. Rail **160** may be generally located above the level of the udder of a dairy cow located in stall portion **122** such that the teats of the dairy cow may be accessible to robotic attacher **150** when suspended from rail **160**. For example, rail **160** may extend across the top of equipment portion **128** of milking box **120** and may be oriented substantially parallel to rear wall **124c**.

Robotic attacher **150** may be communicatively coupled to controller **200** (e.g., via a network facilitating wireless or wireline communication). Controller **200** may cause robotic attacher to attach certain milking equipment to the dairy cow's teats. For example, in certain embodiments, robotic attacher **150** may access a storage area **164** to retrieve preparation cups **166** and/or teat cups **168**. Preparation cups **166** may be adapted to clean the teats, stimulate the flow of milk, and discard fore milk from the teat (e.g., the first few millimeters of milk that may be dirty). Teat cups **168** may be adapted to extract milk from the dairy cow. Preparation cups **166** and/or teat cups **168** attached to extendable hoses may be hung within storage area **164** between milkings to protect the cups from manure and flies. When it is time to milk the dairy cow, robotic attacher **150** may pull preparation cups **166** from storage area **164** and attach them to the dairy cow one at a time, two at a time, or four at a time. After the teats have been prepared, preparation cups **166** may be removed and teat cups **168** may be attached one at a time, two at a time, or four at a time. Once the cups are attached, robotic attacher **150** may withdraw to prevent the dairy cow from

causing accidental damage to the equipment, and the system may proceed with milking the dairy cow.

During milking, pump 170 may pump good milk from teat cup 168 to receiver jar 172 to be stored at a cool temperature. Pump 170 may pump bad milk to milk separation container 174 to be discarded. Milk may be determined to be bad based on testing the milk and/or based on the particular dairy cow from which the milk has been extracted. For example, information retrieved from a database according to the dairy cow's identifier may indicate that the milk should be discarded because the dairy cow is ill or has recently calved.

In certain embodiments, robotic attacher 150 comprises a main arm 152, a supplemental arm 154, a gripping portion 156, and a vision system 158. In certain embodiments, the movement of main arm 152, supplemental arm 154, and gripping portion 156 may be varied in response to signals received from controller 200 (as described in further detail in FIG. 4 below). Although the components of robotic attacher 150 are depicted and primarily described as oriented in a particular manner, the present disclosure contemplates the components having any suitable orientation, according to particular needs.

In order to obtain access to the dairy cow's teats, main arm 152, supplemental arm 154, and gripping portion 156 may work together to facilitate movement in three dimensions, for example, according to an x-axis, a y-axis, and a z-axis. As illustrated, the x-axis extends in the direction of the dairy cow's length (e.g., from head-to-tail), the y-axis extends in the direction of the dairy cow's height, and the z-axis extends in the direction of the dairy cow's width.

Main arm 152 may comprise a vertical arm movably coupled to rail 160. For example, a hydraulic cylinder may movably couple main arm 152 to rail 160. Main arm 152 may traverse rail 160 to facilitate movement of robotic attacher 150 along the z-axis. Accordingly, rail 160 may comprise a track and rollers adapted to support the weight of robotic attacher 150 and to facilitate movement of main arm 152 back-and-forth along rail 160. To prevent wires and hoses from interfering with the movement of main arm 152 along rail 160, guides 162 may be used to loosely hold the wires and hoses in place. For example, guides 162 may comprise U-shaped brackets that allow the wires and hoses to extend a sufficient amount to accommodate movements of main arm 152, but prevent the wires and hoses from dangling in the path of main arm 152.

Main arm 152 attaches to supplemental arm 154. Supplemental arm 154 facilitates movements in any direction. That is, supplemental arm 154 moves in-and-out along the x-axis, up-and-down along the y-axis, and/or from side-to-side along the z-axis. Accordingly, supplemental arm may extend between the rear legs of the dairy cow located within stall portion 122 in order to attach milking equipment to the dairy cow. Supplemental arm 154 may comprise gripping portion 156. Gripping portion 156 may grip a preparation cup 166 or a teat cup 168 for attachment to the dairy cow's teat. Gripping portion 156 may comprise a wrist adapted to perform fine movements, such as pivot and tilt movements, to navigate around the dairy cow's legs and to access the dairy cow's teats. To determine the location of the dairy cow's legs and teats, robotic attacher 150 may use vision system 158. An example embodiment of vision system 158 is described with respect to FIG. 4 below.

FIG. 4 illustrates a detailed perspective view of an example of robotic attacher 150, according to certain embodiments of the present disclosure. Robotic attacher 150 may include a main arm 152, a supplemental arm 154, a gripping portion 156, and a vision system 158. As described

with respect to FIG. 3, robotic attacher 150 may be communicatively coupled to controller 200. Controller 200 may cause robotic attacher to retrieve a cup, such as preparation cup 166 or teat cup 168, move the cup toward a teat of a dairy cow within milking box 120, and attach the cup to the teat.

In general, the teats of the dairy cow may be relatively less visible when looking at the dairy cow from the rear and relatively more visible when looking at the dairy cow from the side. Vision system 158 may facilitate locating the teats from a position to the rear of the dairy cow. Vision system 158 may include multiple cameras, such as a first camera 158a and a second camera 158b. In certain embodiments, cameras 158a, 158b may be coupled to robotic attacher 150 and may be positioned at any suitable location along main arm 152 or supplemental arm 154. As an example, second camera 158b may be coupled to gripping portion 156 of supplemental arm 154 at a location proximate to the part of gripping portion 156 adapted to hold a teat cup, and first camera 158a may be coupled to supplemental arm 154 at a location between second camera 158b and main arm 152.

In operation, controller 200 may access a first image 176 generated by first camera 158a (e.g., from memory module 240) and use first image 176 to determine, using any suitable logic 220, a reference point 178 proximate to the udder, which may then be stored (e.g., in memory module 240). The reference point 178 may be defined relative to certain features of the dairy cow, such as the hind legs and/or the udder. Controller 200 may send a signal to robotic attacher 150 causing robotic attacher 150 to position second camera 158b relative to the reference point 178. Accordingly, second camera 158b may have a consistent point of reference from one milking cycle to the next, which may allow the teats to be located efficiently. Controller 200 may access a second image 180 generated by second camera 158b (e.g., from memory module 240) in order to determine, using any suitable logic 220, a location of a teat.

In certain embodiments, first camera 158a may comprise a three-dimensional camera adapted to generate a first image 176 depicting the rear of the dairy cow, including the hind legs and the udder. Using a three-dimensional camera may facilitate generating a relatively complete image of the rear of the dairy cow within approximately a couple of seconds (e.g., one second), which may be faster than the amount of time it would take for a two-dimensional camera to generate a similar image. In certain embodiments, second camera 158b may comprise a two-dimensional camera adapted to generate a second image 180 depicting at least a portion of the udder to facilitate locating the teats. Second camera 158b may facilitate locating the end of each teat with a relatively high degree of accuracy, such as within a few millimeters. The location of the teat may be used to instruct robotic attacher 150 where to attach the milking equipment.

First camera 158a may begin generating the first image 176 in response to a signal from controller 200 indicating that the dairy cow is positioned proximate to the milking equipment. As an example, the signal may indicate that the rear of the dairy cow has been detected by the backplane 138 of the milking box 120. First camera 158a may begin generating the first image 176 from a starting point and may update the first image 176 in real-time as robotic attacher 150 approaches the dairy cow. The starting point may be determined according to a default position of robotic attacher 150 (e.g., a position determined relative to milking stall 122). Thus, the starting point may be determined without the use of historical data associated with the particular dairy cow being milked. First camera 158a may

communicate the first image **176** to controller **200**, and controller **200** may use the image to locate main features of the dairy cow, such as the right hind leg, the left hind leg, the udder, and/or the tail.

Controller **200** may determine the reference point **178** based on the location of the main features of the dairy cow. The reference point **178** may be defined relative to certain features of the dairy cow, such as the hind legs and/or the udder. As an example, the reference point **178** may be defined between the hind legs and/or below the udder. For example, in certain embodiments, the reference point **178** may be located proximate to a mid-point of the udder. The mid-point of the udder may refer to a point generally located between the front teats and the rear teats in the x-direction and/or between the left teats and the right teats in the z-direction. In certain embodiments, the mid-point of the udder may be estimated prior to determining the precise location of the teats, for example, according to the general size and location of the udder. The reference point **178** may be spaced apart from the dairy cow in the y-direction to minimize the likelihood that second camera **158b** touches the dairy cow. For example, the reference point **178** may be located a few inches below the mid-point of the udder.

Controller **200** may communicate the reference point **178** and/or information describing the main features of the dairy cow to robotic attacher **150**. The reference point **178** may be used to position second camera **158b**. The information describing the main features of the dairy cow may be used to prevent robotic attacher **150** from colliding with the dairy cow when navigating second camera **158b** toward the reference point **178**. Information describing the main features of the dairy cow may include the position of the hind legs, the space between the hind legs, the position of the udder, the height of the udder, the position of the tail, and/or other information. Once robotic attacher **150** has positioned second camera **158b** relative to the reference point **178**, second camera **158b** may begin scanning the udder.

In certain embodiments, second camera **158b** may determine where to look for one or more of the teats according to historical data. The historical data may be received from controller **200** and may describe a previously-determined location of the teats relative to the reference point **178**. The previously-determined location may be based on the location of the teats during one or more previous milking cycles. As an example, the previously-determined location may comprise the location of the teats during the most recent milking cycle. As another example, the previously-determined location may comprise an average of the locations of the teats during a number of previous milking cycles. As another example, the previously-determined location may comprise the location of the teats during a previous milking cycle in which the udder was likely to be as full of milk as the current milking cycle. For example, if eight hours have elapsed since the dairy cow was last milked, the previously-determined location may be determined from a previous milking cycle in which the dairy cow had not been milked for approximately eight hours. Referring to historical data may minimize the area that second camera **158b** must scan in order to locate the teat and may reduce the amount of time required to locate the teat.

Second camera **158b** may communicate the second image **180** to controller **200**, and controller **200** may access the second image **180** to locate the teats of the dairy cow. As described above, in certain embodiments, second camera **158b** may comprise a two-dimensional camera, such as a horizontal laser. If the horizontal laser may scan a portion of the udder other than the teats (e.g., a relatively even surface

of the udder), the scan communicated to controller **200** may generally resemble a substantially solid line. If the horizontal laser scans a portion of the udder that includes the teats, the scan communicated to controller **200** may generally resemble a broken line depicting the teats and the spaces between the teats. As an example, controller **200** may determine that a teat has been located if the scan comprises a broken line in which a solid portion of the line generally corresponds to the width of a teat and the broken portions of the line generally correspond to the proportions of the space between teats.

In certain embodiments, robotic attacher **150** may further comprise a nozzle **182**. Nozzle **182** may be coupled to gripping portion **156**. Nozzle **182** may spray disinfectant on the teats of the dairy cow at the end of a milking cycle, that is, after the dairy cow has been milked and the teat cups have been removed. The disinfectant may be sprayed to prevent mastitis or other inflammation or infection. In certain embodiments, gripping portion may be operable to rotate 180° around the x-axis. During milking, second camera **158b** may be generally oriented on top of gripping portion **156**, and nozzle **182** may be generally oriented underneath gripping portion **156** (i.e., opposite second camera **158b**). Orienting nozzle **182** underneath gripping portion **156** during milking may prevent milk or other contaminants from accessing nozzle **182**. Once the milking has been completed, gripping portion **156** may rotate such that nozzle **182** may be generally oriented on top of gripping portion **156**, and second camera **158b** may be generally oriented underneath gripping portion **156**. Orienting nozzle **182** on top of gripping portion **156** after milking may facilitate spraying the teats with disinfectant from nozzle **182**.

FIG. 5 illustrates an example method **500** for milking a dairy cow using the example milking box **120** depicted in FIGS. 1-4, according to certain embodiments of the present disclosure. In certain embodiments, milking box **120** may be positioned within enclosure **100**, and at least one of the gates **126** of stall portion **122** may be opened to allow the dairy cow to voluntarily enter milking box **120**. At step **502**, presence sensor **132** detects the presence of the dairy cow. Presence sensor **132** communicates a signal to controller **200** indicating the presence of the dairy cow has been detected. Controller **200** sends a signal to an actuator causing gates **126** to close at step **504**. Thus, the dairy cow is prevented from exiting the milking box. Gate closed sensor **134** determines that the gates are closed and communicates a gate-closed signal to controller **200**. In response to the gate-closed signal, controller **200** causes the milking procedure to proceed to the next step. For example, controller **200** sends a signal requesting identification sensor **136** to provide an identifier associated with the dairy cow.

At step **506**, identification sensor **136** reads an ear tag, collar, or other identifier (e.g., an RFID signal) associated with the dairy cow. Identification sensor **136** communicates the identifier to controller **200** to facilitate determining the identity of the cow. At step **508**, controller **200** retrieves information associated with the particular dairy cow according to the determined identity of the dairy cow. For example, information may be retrieved from memory **240**. Controller **200** determines whether to proceed with milking the dairy cow at step **510**. The determination may be made according to the information associated with the dairy cow. For example, if the information indicates that the dairy cow is ill or that the dairy cow has already been milked in the current milking cycle, a determination may be made not to proceed with milking the dairy cow. Alternatively, if the information indicates that the dairy cow is healthy and that it is time to

11

milk the dairy cow, a determination may be made to proceed with milking the dairy cow. If the dairy cow is to be milked, the method continues to step 512. If the dairy cow is not to be milked, the method skips to step 548.

At step 512, controller 200 causes a dispenser to drop feed into feed bowl 130 and positions feed bowl 130. In certain embodiments, feed bowl 130 may move toward the rear of the stall to encourage the dairy cow to back-up toward the milking equipment. Controller 200 determines that the dairy cow is positioned near the milking equipment at step 514. For example, a signal received from backplane 138 of milking box 120 may be used to determine that the dairy cow is positioned near the milking equipment. The signal may indicate when the rear of the dairy cow touches a portion of backplane 138. Upon determining the dairy cow is positioned near the milking equipment (e.g., toward the rear of the stall portion of the milking box), controller 200 instructs first camera 158a to generate a first image 176 of the rear of the dairy cow at step 516. In certain embodiments, first camera 158a may be positioned on robotic attacher 150, and first camera 158a may begin generating the first image 176 in-flight, that is, as robotic attacher 150 retrieves a preparation cup 166 or teat cup 168 from storage and begins moving the cup toward the udder. At step 518, controller 200 receives the first image 176. The first image 176 includes main features of the dairy cow, such as the hind legs, the udder, and/or the tail. Controller 200 accesses the first image 176 to determine a reference point 178 at step 520. As an example, the reference point 178 may comprise a point between the dairy cow's hind legs, a point below the dairy cow's udder, and/or a point proximate to a mid-point of the udder. The mid-point may refer to a point between a first teat and a second teat (e.g., between a left teat and a right teat and/or between a front teat and a rear teat).

At step 522, controller 200 sends a signal causing robotic attacher 150 to position second camera 158b relative the reference point 178. Controller 200 communicates historical data to second camera 158b at step 524. The historical data may comprise data retrieved from a database that indicates a previously-determined location of the teats during a previous milking cycle. The previously-determined location may be described relative to the reference point 178. The method proceeds to step 526 where controller 200 sends a signal causing second camera 158b to generate a second image 180. Second camera 158b may generate the second image 180 by scanning a portion of the udder indicated by the historical data. Second camera 158b may scan the whole teat to facilitate identifying the angle of the teat and the point attachment. At step 528, the controller 200 receives the second image 180 from the second camera. Controller 200 accesses the second image 180 to determine the location of the teats at step 530. The teats may be located in any suitable manner, such as one at a time, two at a time, or four at a time.

Upon determining the location of the teats, controller 200 causes robotic attacher 150 to attach one or more preparation cups 166 at step 532. Second camera 158b may continue to scan the teat while the preparation cup is being attached. Continuing to scan the teat may allow for efficient attachment of the preparation cup. In addition, continuing to scan the teat may allow the preparation cup to be attached at a suitable angle, with the mouthpiece centered on the teat, to prevent folding the teat into the preparation cup. Vacuum pressure may be used to hold the preparation cups in place. Preparation cup 166 facilitates preparing the teat at step 534. Preparation may include cleaning the teat, stimulating the flow of milk, and discarding fore milk from the teat. After each of the teats have been prepared, preparation cups 166

12

may be removed at step 536. For example, the vacuum pressure may be released to remove the preparation cups and the preparation cups may be returned to the storage area.

The method continues to step 538, where controller 200 causes robotic attacher 150 to attach a teat cup 168. For example, teat cup 168 may be retrieved from storage area 164 and navigated to the teat. Second camera 158b may continue to scan the teat while the teat cup 168 is being attached to ensure proper placement of the teat cups. Vacuum pressure may be used to attach the teat cup 168. A sensor may be used to determine the vacuum pressure associated with each teat cup 168. If the vacuum level is low, it may indicate that teat cup 168 has fallen off and needs to be reattached. In certain embodiments, additional teat cups 168 may be attached by re-performing steps 522-530 to locate additional teats.

Once teat cups 168 have been attached to all four teats, robotic attacher 150 may retract and the method may proceed to step 540 to extract milk from the dairy cow. As an example, milk may be extracted by applying pulsation to the teat cup. A sensor may monitor the flow of milk. If the flow becomes low, it may be determined whether teat cup 168 should be removed or reattached. For example, if teat cup 168 has been attached for at least approximately one-and-a-half minutes and/or the amount of milk extracted is consistent with previous milking cycles, it may be determined that teat cup 168 should be removed, otherwise, it may be determined that teat cup 168 should be reattached. When it is determined that teat cup 168 should be removed, controller 200 initiates step 542 to remove teat cups 168. For example, controller 200 may send a signal causing the vacuum pressure to be released to allow teat cups 168 to drop from the teats. Teat cups 168 may be returned to storage area 164 by retracting hoses attached to teat cups 168 or by any other suitable method. Controller 200 then sends a signal to robotic attacher 150 to cause gripping portion 156 to rotate at step 544 in order to orient nozzle 182 toward the teat. The method applies disinfectant to the teat at step 546 by spraying the disinfectant through nozzle 182.

At step 548, controller 200 determines which gate(s) 126 to open. Selectively opening gates 126 may allow the dairy cow to be sorted into a particular region 110 of enclosure 100. The dairy cow may be sorted if its milk tested bad, if it failed to produce a sufficient amount of milk, if information retrieved from a database indicates the dairy cow should be sorted, or for other suitable reasons. Controller 200 sends a signal causing an actuator to open the selected gate(s) at step 550. In certain embodiments, a prod may be used to encourage the dairy cow to exit the milking box. The dairy cow exits the milking box and the method ends.

FIG. 6 illustrates an example method 600 for installation of milking box 120, according to certain embodiments of the present disclosure. The method may begin by positioning walls 124 in order to define stall portion 122. For example, the method positions a front wall 124a at step 602. The method proceeds to step 604 where a rear wall 124c is positioned substantially parallel to front wall 124a. Rear wall 124c may be spaced apart from front wall 124a a suitable distance to accommodate a dairy cow. At step 606, a first side wall 124b is positioned to extend between front wall 124a and rear wall 124c. The first side wall may include one or more gates, such as an entry gate 126a and an exit gate 126b. The method proceeds to step 608 to position a second side wall 124d to extend between front wall 124a and rear wall 124c. Second side wall 124d may be spaced apart from first side wall 124b in order to accommodate a dairy livestock within stall portion 122. Second side wall 124d

13

may or may not include gates **126**. For example, in certain embodiments, second side wall **124d** may comprise a second entry gate **126a** and a second exit gate **126b**. In alternative embodiments, second side wall **124d** may be positioned adjacent a second milking box and may define a boundary between milking box **120** and the adjacent milking box. In step **610**, an equipment portion **128** is positioned to the rear of milking box **120**, adjacent rear wall **124c**. Rear wall **124c** may comprise a backplane **138** adapted to physically contact a mid-flank portion of the dairy livestock when the dairy livestock is positioned proximate to equipment portion **128** of milking box **120**.

At step **612**, a movable feed bowl **130** may be positioned within milking box **120**. Movable feed bowl **130** may be adapted to move from the front of milking box **120** toward the rear of milking box **120** to encourage the dairy livestock to back-up toward backplane **138**. The method may proceed to step **614** to install a plurality of sensors within milking box **120**. Examples of sensors include a presence sensor **132** adapted to detect the presence of the dairy livestock within milking box **120**, one or more gate closed sensors **134** to detect whether gates **126** are closed, and a livestock identification sensor **136** adapted to determine the identity of the dairy livestock present within milking box **120**. At step **616**, a waste grate **140** may be positioned within milking box **120**.

The method may proceed to step **618** to position a rail **160**. Rail **160** may be positioned to extend in a horizontal direction substantially parallel to rear wall **124c**. For example, the horizontal direction may refer to the z-axis illustrated in FIG. 3. In certain embodiments, rail **160** may be positioned proximate to rear wall **124c**. At step **620**, a robotic attacher **150** may be positioned in milking box **120**. Robotic attacher may comprise a main arm **152**, a supplemental arm **154**, including a gripping portion **156**, and a vision system **158**. In certain embodiments, robotic attacher **150** may be positioned in equipment portion **128** of milking box **120** by suspending main arm **152** from rail **160**. Accordingly, main arm **152** may be operable to traverse rail **160** in the horizontal direction. In certain embodiments, one or more guides **162** may be positioned proximate to rail **160**. Guides **162** may be adapted to guide the path of hoses and wires connected to robotic attacher **150** to prevent the hoses and wires from interfering with the movement of main arm **152** along rail **160**. Supplemental arm **154** may be positioned to facilitate selectively extending supplemental arm **154** between the rear legs of the dairy livestock located within stall portion **122**.

The method proceeds to step **622** to position other milking equipment in equipment portion **128** of milking box **120**. Other milking equipment may include one or more preparation cups **164**, teat cups **168**, pumps **170**, milk receiver jars **172**, and/or milk separation containers **174**. The method then ends.

Modifications, additions, or omissions may be made to the systems described herein without departing from the scope of the invention. The components may be integrated or separated. Moreover, the operations may be performed by more, fewer, or other components. Additionally, the operations may be performed using any suitable logic comprising software, hardware, and/or other logic. As used in this document, "each" refers to each member of a set or each member of a subset of a set.

Modifications, additions, or omissions may be made to the methods described herein without departing from the scope of the invention. For example, the steps may be combined, modified, or deleted where appropriate, and additional steps

14

may be added. Additionally, the steps may be performed in any suitable order without departing from the scope of the present disclosure.

Although the present invention has been described with several embodiments, diverse changes, substitutions, variations, alterations, and modifications may be suggested to one skilled in the art, and it is intended that the invention encompass all such changes, substitutions, variations, alterations, and modifications as fall within the spirit and scope of the appended claims.

What is claimed is:

1. A system, comprising:

a robotic arm on which at least one camera is attached;
a memory that stores historical information associated with a dairy livestock, the historical information including a previously-determined location of a teat of the dairy livestock; and

a controller communicatively coupled to the memory and that instructs the robotic arm to move the camera toward the previously-determined location of the teat, wherein the camera generates an image of the teat of the dairy livestock from a position to which it is moved, and the controller determines a current location of the teat of the dairy livestock based at least in part on the image;

wherein the robotic arm attaches milking equipment to the teat between the hind legs of the dairy livestock based at least in part upon the determined location of the teat.

2. The system of claim 1, wherein the milking equipment comprises a milking cup.

3. The system of claim 1, wherein the controller receives identification information for the dairy livestock and accesses the historical information for the dairy livestock based at least in part on the identification information.

4. The system of claim 1, wherein the camera comprises a three dimensional camera.

5. The system of claim 1, wherein the dairy livestock is located in a milking stall.

6. The system of claim 1, wherein the previously-determined location of the teat is relative to a reference point.

7. The system of claim 6, wherein the reference point is relative to at least one of a hind leg of the dairy livestock or a mid-point of an udder of the dairy livestock.

8. The system of claim 1, wherein the previously-determined location of the teat is based on a previous milking cycle for the dairy livestock.

9. The system of claim 1, wherein the previously-determined location of the teat comprises an average of the locations of the teat during a number of previous milking cycles.

10. The system of claim 1, wherein the previously-determined location of the teat comprises a location of the teat during a previous milking cycle in which the udder of the dairy livestock was substantially as full of milk as a current milking cycle for the dairy livestock.

11. A method, comprising:

storing historical information associated with a dairy livestock, the historical information including a previously-determined location of a teat of the dairy livestock;

moving a camera toward the previously-determined location of the teat using a robotic arm;

using the camera to generate an image of the teat of the dairy livestock from a position to which the camera is moved;

determining a current location of the teat of the dairy livestock based at least in part on the image; and

attaching milking equipment to the teat between the hind legs of the dairy livestock based at least in part upon the determined location of the teat.

12. The method of claim 11, further comprising:
receiving identification information for the dairy live- 5
stock; and

accessing the historical information for the dairy livestock based at least in part on the identification information.

13. The method of claim 11, wherein the camera comprises a three dimensional camera. 10

14. The method of claim 11, wherein the previously-determined location of the teat is relative to a reference point.

15. The method of claim 14, wherein the reference point is relative to at least one of a hind leg of the dairy livestock 15
or a mid-point of an udder of the dairy livestock.

16. The method of claim 11, wherein the previously-determined location of the teat is based on a previous milking cycle for the dairy livestock.

17. The method of claim 11, wherein the previously- 20
determined location of the teat comprises an average of the locations of the teat during a plurality of previous milking cycles.

18. The method of claim 11, wherein the previously-determined location of the teat comprises a location of the 25
teat during a previous milking cycle in which the udder of the dairy livestock was substantially as full of milk as a current milking cycle for the dairy livestock.
